This comprehensive guide will delve into the fundamentals of the Doppler shift, how the Gizmo tool functions, and the essential answers and concepts associated with the advanced Gizmo exercises.

Understanding the Doppler Shift

What Is the Doppler Effect?

The Doppler effect is a phenomenon observed when the frequency of a wave changes for an observer due to the relative motion between the source of the wave and the observer. It is named after Christian Doppler, who first described this effect in 1842. The effect is most commonly experienced with sound waves but also applies to electromagnetic waves such as light.

In everyday life, the Doppler effect explains why the pitch of a passing siren appears higher as it approaches and lower as it recedes. Similarly, astronomers observe redshift and blueshift in light from celestial objects, revealing their motion relative to Earth.

Key Variables in the Doppler Effect

Understanding the Doppler shift involves several critical variables:

- **f?**: The original frequency emitted by the source.
- **f'**: The observed frequency by the listener.
- **v**: The velocity of the source or observer relative to the medium.
- **v_s**: The velocity of the source.
- **v_o**: The velocity of the observer.
- **v_m**: The velocity of the medium (for sound waves in air, for example).

Common Questions and Their Answers

Below are some typical questions encountered in the advanced Gizmo and their corresponding key concepts:

- **How does the relative motion of source and observer affect the observed frequency?**
Answer: When the source and observer move closer, the observed frequency increases (blueshift). When they move apart, the frequency decreases (redshift).

- **What is the formula for the Doppler effect with a moving source and a stationary observer?**
Answer: $f' = \frac{f_0}{1 - \frac{v_s}{v_m}}$ (for source moving towards stationary observer), where v_s is the source velocity and v_m is the wave speed in the medium.

- **How does the wave speed in the medium influence the Doppler shift?**
Answer: The wave speed determines the baseline frequency; higher wave speeds result in less pronounced frequency shifts for the same relative velocities.

- **What is the significance of the redshift and blueshift in astrophysics?**
Answer: Redshift indicates that celestial objects are moving away, while blueshift shows they are approaching. These observations help determine the universe's expansion and the movement of stars and galaxies.

Problem: A police car emits a siren at a frequency of 1000 Hz. The car approaches a stationary observer at 30 m/s, while the speed of sound in air is 340 m/s. What is the perceived frequency?

Solution:

- Known:
- $f = 1000\, \mathrm{Hz}$
- $v = 340\, \mathrm{m/s}$
- $v_s = 30\, \mathrm{m/s}$ (approaching, so positive in the formula)
- $v_o = 0\, \mathrm{m/s}$

- Using the Doppler formula for a moving source approaching stationary observer:

\[

f' = \frac{v}{v - v_s} \times f

\]

- Calculation:

\[

f' = \frac{340}{340 - 30} \times 1000 = \frac{340}{310} \times 1000 \approx 1.0968 \times 1000 \approx 1096.8\, \mathrm{Hz}

\]

Example 2: Moving Observer Receding from Stationary Source

Problem: A stationary source emits sound at 800 Hz. An observer moves away at 15 m/s. The speed of sound is 340 m/s. Find the perceived frequency.

Solution:

- Known:
- \(f = 800\, \mathrm{Hz}\)
- \(v = 340\, \mathrm{m/s}\)
- \(v_o = 15\, \mathrm{m/s}\) (receding, so subtract in the denominator)
- \(v_s = 0\, \mathrm{m/s}\)

- Using the formula for a moving observer:

\[

f' = \left(\frac{v - v_o}{v} \right) \times f

\]

- Calculation:

$$
f' = \left(\frac{340 - 15}{340} \right) \times 800 = \left(\frac{325}{340} \right) \times 800 \approx 0.9559 \times 800 \approx 764.7\, \mathrm{Hz}
$$
